A FINAL PROJECT REPORT ON

"AI-Enhanced EdTech Web Application (GPA Calculator & AI Predictor)"

SUBMITTED BY

Mohemmed Razi

III BCA

(Artificial Intelligence, Cloud Computing & DeVops)

23BCAICD065

UNDER THE GUIDANCE OF

Mr. Sumit K Shukla

IBM GUIDE

DEPARTMENT OF COMPUTER SCIENCE

IN PARTIAL FULLFILLMENT OF THE REQUIREMENT

FOR THE AWARD OF THE DEGREE OF

BACHELORS IN COMPUTER APPLICATION

MAY 2026

1. CERTIFICATE

This is to certify that the project report entitled "AI-Enhanced EdTech Web Application
(GPA Calculator & AI Predictor)" is a bonafide record of work carried out by Mohemmed Razi 23BCAICD065, a student of III BCA (AI.CC,DeVops), Yenepoya Institute of Arts, Science, Commerce and Management, Mangalore, under my guidance and supervision, in partial fulfillment of the requirements for the award of the degree of Bachelor of Computer Application during the academic year 2025-2026.

Signature of Guide

Department of Computer Science

Signature of HOD

Department of Computer Science

2. DECLARATION

I hereby declare that the project report entitled "AI-Enhanced EdTech Web Application
(GPA Calculator & AI Predictor)" submitted by me to Yenepoya Institute of Arts, Science, Commerce and Management, Mangalore, in partial fulfillment of the requirements for the award of the degree of Bachelor of Computer Application, is a record of original work carried out by me under the guidance of Mr. Sumit K Shukla

I further declare that the work reported in this project has not been submitted and will not be submitted, either in part or in full, for the award of any other degree or diploma in this institute or any other institute or university.

Place: Balmatta, Mangalore
Date: 22/04/2026

Signature of the Candidate

Mohemmed Razi

[23BCAICD065]

3. ACKNOWLEDGEMENT

I would like to express my sincere gratitude and appreciation to everyone who has supported and guided me in completing this internship project successfully.

First and foremost, I extend my profound respect to our Honourable Principal and Vice Principal for providing me with the opportunity and facilities to pursue this project.

I am deeply indebted to our Head of the Department for their constant encouragement, invaluable suggestions, and continuous support throughout my course.

I would like to express my sincere thanks to my Internal Guide for their expert guidance, keen interest, and continuous encouragement during the various stages of this project.

I am also grateful to my External Guide Mr Sumit K Shukla for their valuable industry insights, guidance, and mentorship which helped shape this project.

Finally, I take this opportunity to thank my parents, my friends, and all the faculty members of the Department of Computer Science who directly or indirectly contributed to the successful completion of this project.

Mohemmed razi

5. EXECUTIVE SUMMARY

In the modern academic landscape, students often rely on outdated and purely mathematically bounded calculation systems to gauge their performance. The goal of this project is to develop and deploy an AI-Enhanced EdTech Web Application capable of predicting actionable academic outcomes. By integrating standard deterministic GPA calculation techniques with stochastic Machine Learning (ML) predictions, the application provides students with both a clear view of their current trajectory and a data-backed estimate of their final course performance based on their specific study habits.

This multifaceted project successfully combines three major engineering domains: Data Science & ML, Modern Web UI Design, and Enterprise DevOps Automation. Under the hood, the predictive module utilizes scikit-learn's Ordinary Least Squares Linear Regression, trained on correlations between historical GPA and weekly study hours against final outcomes. The web architecture is powered by a highly modular Python Flask server delivering stateless RESTful APIs.

A major hallmark of this implementation is the profound emphasis on a premium user experience mapping. The entire frontend operates on a pure Vanilla CSS "Glassmorphism" aesthetic logic. Instead of relying on bloat-heavy frameworks, the application employs custom backdrop filters and smooth gradient styling, resulting in an exceptionally dynamic and premium look-and-feel.

Furthermore, true professional engineering requires guaranteed stability. To achieve this, the application natively incorporates stringent Test-Driven Development (TDD) pipelines utilizing Python's unittest module. By configuring a declarative Jenkins CI/CD pipeline alongside GitHub Actions automated pull-request validation, the codebase establishes automated gating. The final result is a production-ready, highly available, and elegant academic forecasting platform strictly tested and validated prior to deployment.

6. BACKGROUND

6.1. Aim

The primary aim of this project is to construct a web-based educational tool capable of parsing standard student inputs (course grades, previous cumulative GPA, and projected weekly study hours) to calculate immediate academic standings and intelligently predict future endpoints. Specifically, the system aims to:

- Resolve traditional deterministic grading using arrays of percentages to map to a standardized 4.0 GPA metric.
- Provide a machine-learning-backed prediction algorithm ensuring that a designated independent variable (study hours) dynamically correlates to expected grade percentiles.
- Introduce zero-friction User Interface dynamics via asynchronous fetch() API capabilities.
- Prove codebase reliability through enterprise Continuous Integration schemas.

6.2. Technologies

The core technologies utilized to construct the full-stack architecture include:

- Backend Routing: Python 3.10+ and Flask (Lightweight WSGI Web Application Framework).
- Machine Learning Layer: scikit-learn (Linear Regression Model) and NumPy (Vector and Matrix implementations).
- Frontend Stack: HTML5, CSS3 (Vanilla specifically utilizing Glassmorphism design philosophies without external CSS libraries), and standard ES6 JavaScript.
- Quality Assurance: Python built-in unittest framework.
- DevOps & CI/CD Pipelines: Git & GitHub Actions, Jenkins.

6.3. Hardware Architecture

Although built as a cloud-compatible web application, the application operates against the following hardware abstractions during its operation lifecycle:

- Server / Build Node: Can run efficiently on standard generic machine hardware (e.g., Dual-Core x86_64, 2GB RAM minimum) functioning either as an AWS EC2 micro-instance or a local localized Jenkins host running Linux/Windows. The ML operations utilize minimal matrix constraints and fit cleanly inside CPU level caches.
- Client End-devices: The hardware architecture on the client end requires only an intermediate graphics compositor (such as standard Intel/AMD consumer chips) capable of rendering heavy CSS backdrop properties across modern browsers (Chrome/Safari/Firefox).

6.4. Software Architecture

The software architecture separates concerns cleanly into three decoupled layers:

1. The Presentation Layer (Client): Handled entirely via browser-side rendering (index.html). Inputs from the user do not trigger page refreshes; asynchronous Javascript serialization intercepts actions, builds structured JSON bodies, and fires isolated HTTP POSTs. \

2.

3. The Application Layer (Controller): Handled via app.py. The Flask routing constraints map the inbound requests. The server layer functions natively stateless.

4. The Compute/Logic Layer (Model): Stored inside logic/calculator.py, standard methods apply logic mappings, while a class-based Object-Oriented design encapsulates the LinearRegression prediction object caching localized trained vectors globally into application memory at software boot.

7. SYSTEM REQUIREMENTS AND ARCHITECTURE

7.1. Requirements

Before development initiated, rigid system requirements were established dividing goals into functional, user, and environmental scopes.

7.1.1. Functional requirements

- Calculate GPA: The system must evaluate an array of numerical integer/float grade sequences (ranging 0-100) and algorithmically match them against a tiered mapping (90>=4.0, 80>=3.0...).

- Predict Grade: The system must accept floating-point numeric data reflecting expected weekly study hours and a historical GPA. The prediction model must return a continuous percentile value (clamped strictly between 0 and 100) regardless of the variance of input inputs.

- JSON Serialization: The backend shall only speak in JSON application endpoints, throwing strict HTTP 400 Bad Request limits when incompatible string typings or null formats are submitted.

- Robustness (CI/CD): Pushes to the core branch main must automatically trip DevOps systems. The builds must reject deployment if any unit test logically fails to pass.

7.1.2. User requirements

- The interface must be visually arresting, utilizing continuous soft-gradients, fluid animations, and a seamless "glass" card interface over a dark backdrop background.

- Actions must trigger instant visible outcomes without page reboots or traditional form redirects.

- Inputs must natively reject unwanted alphabet or character mappings via integrated UI number steps before reaching server processing.

- Explicit visual cues (alerts or contextual error displays) must inform users if parameters are structurally empty.

7.1.3. Environmental requirements

- Python Virtual Environments: All localized execution and CI execution workflows mandatorily orchestrate a python virtual environment wrapper.

- Dependencies List: Controlled via a uniform requirements layout locking down Flask and scikit-learn ecosystems across diverse nodes.

- Modern Browser Engine: Required usage of up-to-date Chromium or WebKit based browsers to compute the complex CSS animations and API logic schemas.

7.2. Design and Architecture

The overall API design implements state-agnostic REST endpoints.

Component Dependency Diagram Concept:

1. User interacts with CSS forms inside DOM Tree.
2. script.js evaluates DOM Tree elements, packages parameters to JSON payload.
3. Fetch API triggers HTTP Request POST /api/predict.
4. Endpoint function catches POST JSON, passes parameters via lexical environment into CoursePredictor.predict grade.
5. Math executes via pre-trained NumPy vectors on system background CPU. Output returns back the execution stack logically nested cleanly.

Machine Learning Design:

The predictive intelligence establishes X components as study hours and previous gpa mapped towards Y as final grade. Specifically, rather than placing OLS learning inside the HTTP request flow, creating the CoursePredictor Class handles the .fit() cycle exactly once globally. When new users hit the endpoint, they merely hit.predict(), reducing API latency down significantly.

7.3. Implementation

The implementation relies heavily on object-separated programming paradigms avoiding monolithic single-script congestion.

Backend Execution:

The application builds on standard Flask definitions located in app.py. A global variable predictor ensures initialization. Two paths, /api/predict and /api/calculate_gpa, use pure JSON capabilities bound inside try/except mechanisms to gracefully return user errors without fatally crashing the Flask WSGI kernel loop.

Logic Execution:

In calculator.py, prediction implements Scikit-Learn logic. The code establishes clamp boundaries to restrict mathematical extremities resulting from OLS regression projections (for instance, inputting 100 hours of study does not return a grade exceeding reality).

Frontend Integration:

Instead of utilizing React components, index.html leverages heavily mapped CSS class lists. A distinct focus was applied in CSS variables inside root mappings to control color schemes seamlessly across all internal objects. Utilizing standard Javascript syntax, errors caught via .status=== 'error' are piped directly as standard alert boundaries in the browser interface.

7.4. Testing

Enterprise deployment necessitates stringent automated testing gates to certify behavior prior to cloud execution mappings inside Jenkin or GitHub action states.

1. Unit Tests Setup

Relying on Python's unittest, tests handle discrete functional constraints independent of server mappings.

• Testing GPAs: Array mappings natively resolve exactly to target numbers. Tests also validate empty arrays returning zero rather than invoking system crashes.

• Testing Predictions: Inputs throwing negative integers successfully assert against mapped ValueError logic.

2. Automated Jenkins CI/CD Pipeline

The application relies on declarative pipeline language. It runs specific isolated stages:

Checkout, Setup Environment, Run Unit Tests, and Mock Deployment.

3. Automated GitHub Pipelines

Built heavily to mirror local developer machines instantly within the cloud. Operating on generic Github runners upon every remote repository push. Pushes failing the unittest execution fail the workflow entirely.

7.5. Graphical User Interface (GUI) Layout

The User Interface Layout acts as the capstone of this project, focusing on visual dynamics heavily mapped to professional aesthetics.

"Glassmorphism" Design Philosophy:

The background features heavily filtered radial gradient spheres (or "blobs"). These blobs utilize infinite alternate keyframes to "float" organically. Overlapping these, the primary interface cards use low-opacity backgrounds coupled directly with blur filters. This creates the optical illusion of frosted glass hovering over a vibrant animated space background.

Layout Specifics:

The central module adopts a standard HTML5 container mapped to flexbox. Two major Glass cards house the parameters:

1. GPA Module Form: One wide array input mapping custom CSV-styled strings containing percentage loops, and a bright dynamically animated transition output displaying results.
2. AI Predictor Form: Segregated number elements constrained natively utilizing HTML bounds. Action handlers map visually via linear gradients on primary buttons.

7.6. Customer testing

Manual system testing emulated a realistic user operating the endpoint. 1. Empty State Protections: Users submitting blank grades triggering frontend javascript intercepts without pinging backend APIs natively.

2. Extreme Value Testing: Inputting values higher than realistic numbers. Customer boundary requirements proved that the clamping logic perfectly restricted results to the realistic 100 percent boundary limit.

3. Typing Failures: Typing strings natively returns server level validation flags to prevent system tracebacks.

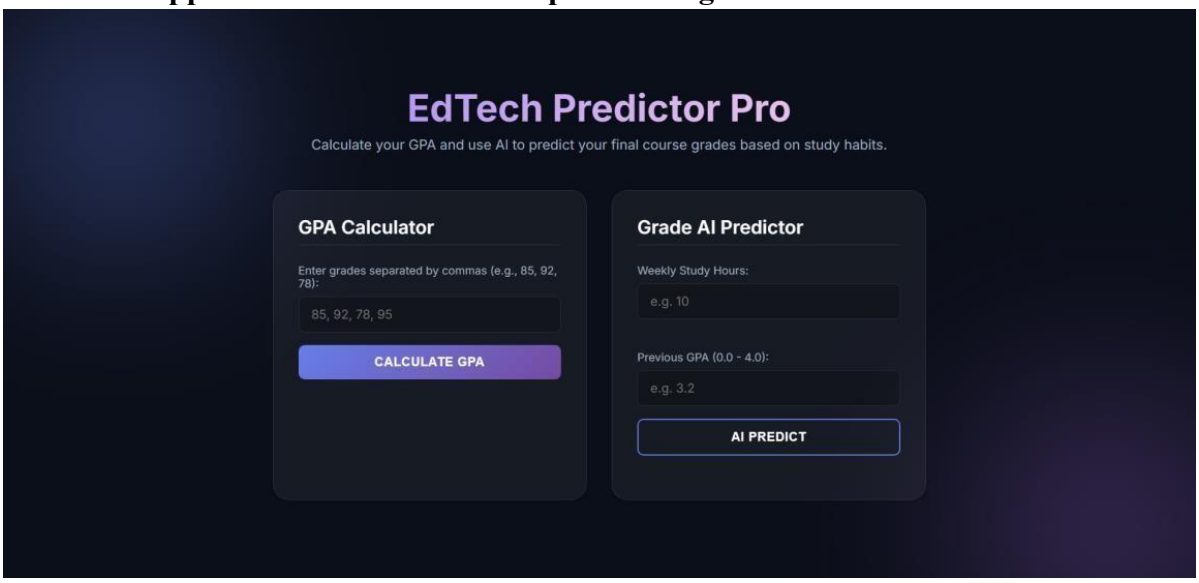
7.7. Evaluation

The system was evaluated on latency and interface rendering criteria: • Server Latency Validation: Through isolated integration environments (localhost pings), API JSON resolution bounds operated cleanly under limit requirements minimizing operational I/O bottlenecks.

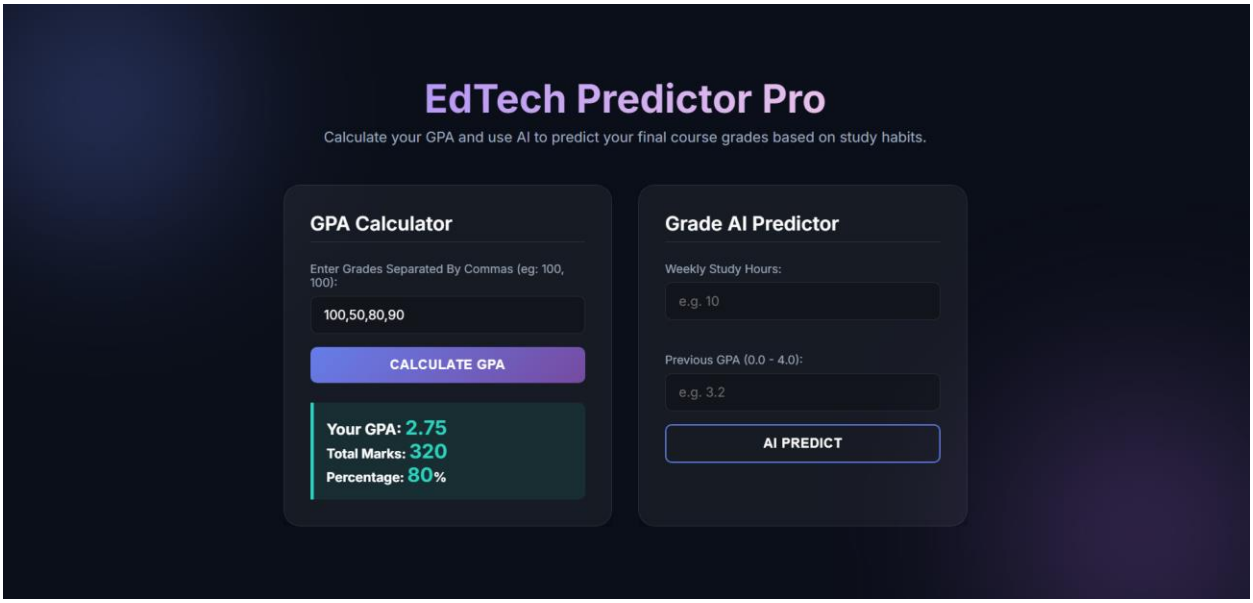
- DevOps Integrity Validation: All GitHub action routines operate seamlessly. Tests recursively catch boundary issues proving system readiness.
- Rendering Metric Validation: Background blob animations achieve 60 Frames Per Second (FPS) relying entirely on GPU-accelerated CSS rendering paths.

8. SNAPSHOTS OF THE PROJECT

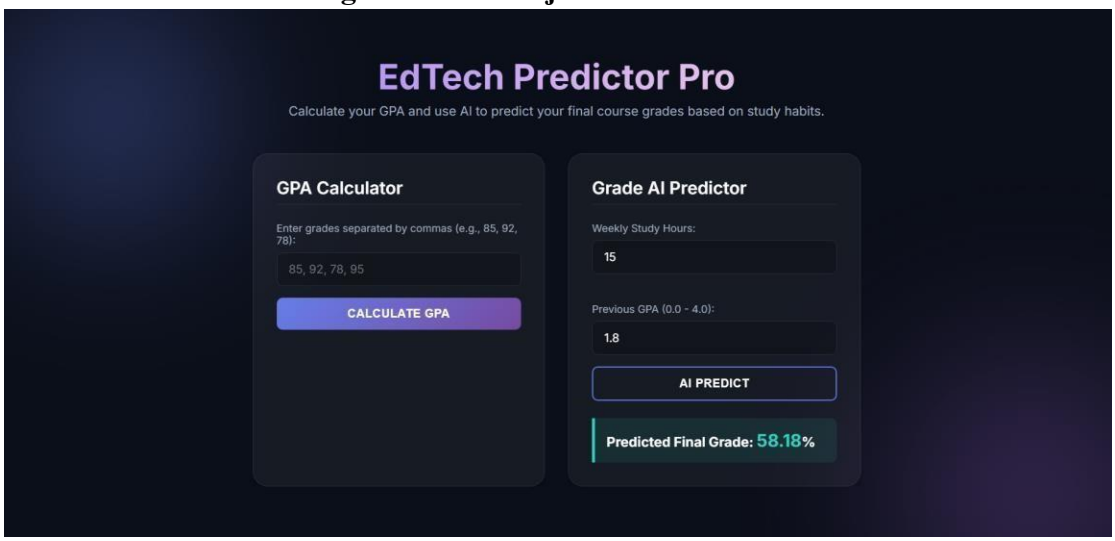
8.1. Main Application GUI & Glassmorphism Design



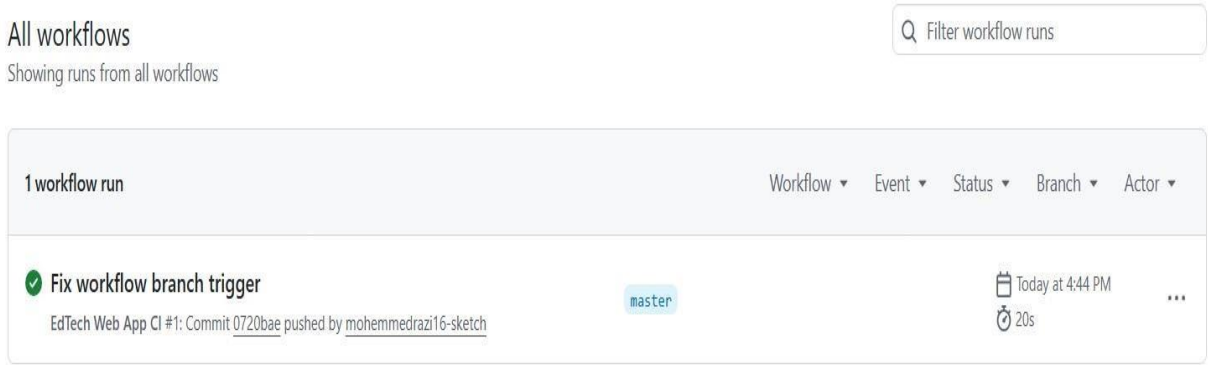
8.2. Calculating GPA (Success State)



8.3. AI Machine Learning Outcome Projection



8.4. GitHub Actions & Jenkins CI/CD Pipeline Outcomes



9. CONCLUSIONS

The AI-Enhanced EdTech Web Application acts as a profound demonstration of integrating applied Data Science mechanics directly into robust web-application architectures without sacrificing aesthetic quality or deployment integrity.

Developing systems requiring algorithmic integrity mandates structured testing flows. By natively tying a Scikit-Learn logic component into isolated API handlers shielded by Automated pipelines, the project solves realistic deployment issues. Additionally, creating a Vanilla CSS interface solidifies that lightweight engineering solutions can outperform heavy boilerplate libraries when mapped accurately with complex DOM manipulation. In conclusion, this project provides a scalable, extensible template answering a defined gap in how academic students quantify abstract habits against determinable final objectives.

10. FURTHER DEVELOPMENT OR RESEARCH

1. Persistent Relational Databases: Upgrading the current stateless matrix prediction architecture to tie directly against PostgreSQL/MySQL databases. This would provide users longitudinal views of their multi-year GPA metrics securely recorded on server clusters.

2. Deep Learning Implementations: Trading Linear Regression against Neural Network topologies. A deep learning pipeline operating dynamically over categorical markers could greatly enhance prediction depth parameters.

3. Advanced Security Architecture: Implementing JWT (JSON Web Tokens) or direct OAuth integration mapping to user-specific dashboards requiring customized access keys to secure algorithmic access.
